

Micro Sized ChatGPT CHEATING DEVICE

ASHWINI KUMAR SINHA

ChatGPT is one of the most famous and advanced AI tools today, widely known and frequently used. It can generate code, websites, pictures, and much more. But can this powerful tool fit into a tiny device? Can it integrate with IoT sensors? Can it interface with electronic devices? This device aims to achieve this. You can make a ChatGPT device that displays answers on an OLED when asked using either the web serial or USB serial. The device measures just 3cm, making it the smallest ChatGPT device. It provides quick assistance and can function as a cheating device.

BILL OF MATERIALS

Components	Description	Quantity
IndusBoard	3cm sized development board	1
Battery	3.3V	1
OLED/LCD display	SSD1306/ GC9A01	1

Fig. 1: Author's prototype

Fig. 1 shows the author's prototype that works with WebSerial. The components needed for the device

are listed in Bill of Materials table.

The IndusBoard is used to connect to wi-fi and ChatGPT API and

host the web serial server. Questions can be asked using the WebSerial, and these are transferred to the ChatGPT API. The answer is then displayed on the OLED screen connected to the board.

Configuration

First, create the ChatGPT API using the OpenAI link <https://openai.com/index/openai-api>. Navigate to API keys and create a new API key. Save this key and do not share it with anyone. Add payment billing information to use the API. First-time users receive a \$5 credit for free, so usage depends on whether the user is new or existing. Fig. 2 shows the API configuration, and Fig. 3 shows how to create a new key. Next, install the ESP32 board in Arduino IDE, and then install the
