

How do you ensure that the IP you design for different clients is compatible with their existing systems?

When commencing the design process, it all begins with a set of specifications or rules. These rules serve as standards that everyone adheres to. For example, when creating a product for navigation, there are rules both in India and internationally. Similarly, for GNSS (like GPS), there are diverse rules like NavIC, GPS, Galileo, and so on. These rules are mostly similar but may have small differences. So, when we create a product for a client, we make sure we follow the rules and requirements they give us.

Our design process proceeds from the top to the bottom. Initially, our system team dissects the specifications into smaller segments. Subsequently, our designers work on these segments individually, ensuring com-

pliance with the specifications. We use special tools to simulate and test these segments for rule adherence. Once each segment is designed and tested, we integrate them to form the whole system. Subsequently, we conduct comprehensive testing to ensure optimal performance. Before commencing the design, we must understand how the product will be used, its power requirements, and other details. Multiple tests are conducted to validate that everything aligns with our expectations from simulations. However, if our initial assumptions are wrong, real test results may significantly vary from our expectations.

How do you address potential issues?

We address issues at the outset of the design process, not later. We cannot afford to spend three or four

months designing something and then realise we overlooked factors like interference, noise, and other issues. For instance, if there's a shared or noisy power supply, we must consider that from the project's inception. Our approach involves not only designing the system but also creating test setups for various scenarios. We account for all these factors before finalising the design and progressing to subsequent stages.

What is the smallest size that you have achieved?

Our silicon is like a tiny coil, about 2 millimetres in size. When producing prototypes, we use a chip with 32 pins because we need extra ports for testing and other purposes. However, for mass production, we aim to use a smaller version with perhaps 16 pins or even 4 pins, to enhance efficiency. **EFY**

Wanna Be Your Own Boss?

DO OPEN SOURCE.

www.opensourceforu.com

Demand for Open Source is sky rocketing. Be it for managing IT infrastructure or development of software—Open Source solutions are what customers are seeking.

All you need to do is develop expertise in an Open Source stack, and then build a team around it!

And, Open Source For You can be your friend and a guide through this journey.
