

Fig. 7: Encrypted data message

Fig. 8: The data shows after decryption when the right implanted chip is scanned

previously installed the RFID and scanner in a DIY project published in December issue, we are modifying and creating new software for this process. You can use different implantables with writable memory, as mentioned earlier.

EFY note. For actual deployment, additional security certifications and complex coding are necessary.

First, install the encryption library by running the following command in the terminal:

```
pip3 install cryptography
```

Next, create the code that saves

secret messages and files, encrypting the data. The encryption code utilises the cryptography library. Insert the secret message and text you want to encrypt, then run the code to save the data and secret message in encrypted format.

Create a code that scans the implanted chips, checks if it is the correct implanted chip UUID, and then decrypts the data and message file, displaying it. Depending on the RFID implantable chip used, you can either use the RDM Python library (refer to author's article in December issue) or the serial library.

Adjust the serial port name and baud rate in the code accordingly.

Testing

Write the message and check the file you want to encrypt in the 'encrypt.py' code. Run the code to encrypt the data and save it. Connect the RFID chip scanner. Set the port and baud rate in the 'decrypt.py' code for the scanner's serial port. Run the code to prompt the scan. If the correct chip is scanned, it will decrypt the data and message.

Fig. 5 shows how the implanted chip LED glows when scanned inside the body. Watch demo at <https://>

EFY note. This article is for educational purposes only, and no animals or humans were harmed in the experiment. Implanting a chip inside the body may pose health risks, so it is recommended to use the article only for learning purposes. Keep chips away from kids below 18. For any actual in-body implant, consult with doctors and experts. **EFY**
