

The ‘Big Little’ Problem In HARNESSING AI To Revolutionise Workplaces

As AI advances, exemplified by ChatGPT-4, job roles are evolving. Yet, there is significant potential to enhance productivity by synergising human intelligence with AI. Concurrently, efforts to resolve chip-related challenges persist, driving the continuous improvement of electronics for a promising future.

Imagine a world where artificial intelligence (AI) not only emulates human intelligence but also enhances its performance with each interaction, constantly improving over time. This concept might seem familiar as AI has been a topic of discussion for decades, yet recent developments are propelling us towards a pivotal moment in its evolution. One such indicator of this shift is a report by Goldman Sachs, which suggests a staggering potential loss of 300 million jobs worldwide due to AI advancements. Despite these alarming predictions, there is a silver lining: AI has the power to significantly boost efficiency and effectiveness in our work—as a digital assistant, challenging the notion that it could replace us outright.

As we delve deeper into the realm of AI, recent updates such as the release of ChatGPT-4 and its predecessor, ChatGPT-3.5, exemplify the rapid progress in generative AI models. These advancements are not just technical milestones; they represent a paradigm shift, augmenting human intelligence and driving productivity. This ongoing evolution echoes the transformative impact of the Industrial Revolution, suggesting that AI could enable unprecedented levels of automation in various business processes, from operations, sales and marketing to accounting, finance, and beyond.

A new era of productivity

Every piece of data around, from weather updates, supply chain advancements or
