

Fig. 9: Real-time location on a smartphone

and GSM modules. The default baud rate for GSM is 4800 and for GPS is 9600. Then get the GPS location and send it to the set number at one-minute time interval.

The time interval can be adjusted. Message-based location sending can also be set; like when sending a message to the device, give the location to the device and reply with a location map link. Various customisations can be made in the code. Fig. 5 shows the snippet of the source code.

Construction and testing

For the construction of the tracker, all the components can be soldered according to the circuit diagram as shown in Fig. 2. After soldering the components, the GSM module can

Fig. 10: GPS tracker showing location of the device

be placed and fixed either on the top or bottom of the IndusBoard and then the GPS module can be fixed as shown in Fig. 6 and 7.

Now a keyring and tag case can be designed over the tracker and attached anywhere for use. Fig. 8

shows the GPS tracker ring.

Now, connect the power to the tracker with a 3.3V rechargeable battery. Insert the SIM card with a message pack in the GSM module.

After a few minutes, when the SIM module gets connected with a network provider, it starts sensing the real-time location on the phone as shown in Fig. 9. Tapping on that link reveals the location on Google Map. Fig. 10 shows the GPS tracker showing the location of the device. **EFY**
