

THERMAL CAMERAS: Game-Changers In Making Roads Safer

By integrating these smart cameras into cars, we are looking at a future with fewer pedestrian accidents and safer streets for everyone

Thermal imaging can see vulnerable road users (VRUs) both day and night at distances that allow vehicles to stop when collision is threatened. Detection, classification, and measurement of range can all be derived from an image supplied by a single thermal camera

In recent times, we have all become increasingly concerned about pedestrian safety at night. It is a topic that is making headlines worldwide, with a New York Times article shedding light on the alarming rise in nighttime pedestrian fatalities, a trend that has been on the increase since the 2010s. Shockingly, we are talking about approximately 700,000 pedestrian deaths each year, and a sizable portion of these tragedies happen when it is dark outside.

This growing concern is leading international regulatory bodies, not just in the United States but also in the

EU and Asia-Pacific regions, to consider strict rules for car makers. These rules are all about making sure vehicles have advanced systems that can detect pedestrians, even in low-light conditions. The urgency of this issue is further underlined by Forbes magazine and Vox, which report on innovative solutions like thermal imaging, and the sobering fact that pedestrian deaths in the US have reached their highest point in 40 years.

So, what is at the core of these solutions? It is the complex technology of vehicle sensor suites. Modern vehicles are equipped with advanced driver assist
