

of Intel devices, from CPUs to edge devices like Raspberry Pi or AI-enabled watches. The open source nature encourages broader participation in solving industrial challenges using proprietary hardware architecture, fostering a global community of developers addressing various use cases and problems. A remarkable business model, isn't it!

Profiting from open source

Intel's stance isn't centred around monetising open source directly, like many other businesses. Instead, we encourage the use of open source tools, integrated into a hardware system, thereby creating a demand for purchasing necessary hardware, in this case Intel's proprietary hardware. This approach caters to different needs—while some users might opt only for the open source components, others may prefer to leverage the entire ecosystem, making it a flexible model that accommodates a variety of preferences and requirements.

However, with time Intel hasn't limited its flexible model just to proprietary chips. Since 2023, the chipmaker has optimised its models to run on ARM processors, extending to Apple's Macs and other platforms as well, all along working to understand, learn, and evolve the product to enhance its performance. The goal is to make Intel's open models compatible across various hardware platforms, which is not fully realised

yet. At the outset, the focus is on Intel's range of hardware, such as GPUs and CPUs, prioritising making the model run effectively on these devices and optimising performance, and gradually extending this capability to other devices as well.

While there is a possibility that, in the future, OpenVINO might be compatible with all hardware types, currently, there aren't any immediate plans to extend OpenVINO across the entire hardware spectrum. It's important to note that while the toolkit is open sourced, the model optimised by Intel may or may not be.

Depending on the type of model, if someone finds value in one of the licences, there is often a cost associated with maintaining quality. This cost comes with the need for different protocols and standards that are integrated into a system.

In the context of artificial intelligence, compliance regulations vary across different regions. For instance, in the European Union, GDPR is a major compliance factor that needs to be considered even before building an AI solution or addressing a problem statement with AI, making compliance incredibly crucial, especially when scaling up the open source software solution.

So, when should a business limit the involvement of open source in a product's lifecycle? While open source has significantly contributed to the development and evolution

of AI/ML and cloud technologies, fostered innovation, and problem-solving, determining the balance between contributing to the open source community and maintaining a competitive edge involves multiple approaches.

The decision to limit open source involvement depends on the product's lifecycle. A developer can sense when a product is reaching its peak. Like any technology, each product has a saturation point. Currently, as AI is rapidly evolving, we don't foresee reaching this point with OpenVINO anytime soon. However, it's always a possibility. Ultimately, the decision is influenced by time and the direction the industry takes.

Open source is endlessly powerful because of the unpredictability and the breadth of innovation it fosters. With proprietary technology giants venturing into the fields of open source, a broader community of developers is now getting engaged in addressing the challenges, thus allowing them to tap into a wider pool of talent, while continuing to serve their primary customers. By providing open source software tools that complement their hardware, chipmakers can make their products more accessible and attractive to developers and businesses. **EFY**

TRACO POWER

www.tracopower.com

THN 15UIR and THN 20UIR

15 and 20 watt 12:1 ultra-wide input voltage range DC/DC converters

- Compact 1"x1" housing
- Ultra-wide 12:1 input voltage range: 9–75, 14–160 VDC
- –40°C up to +70°C natural convection cooling without derating
- EN 50155, EN 45545-2 and EN 61373 certified

EN 50155
EN 45545-2
EN 61373

UL 62368-1

IEC 62368-1
