data centres in a container.”

IaaS can be delivered via a public cloud, a private cloud, a community cloud or a hybrid cloud. Public IaaS cloud allows multiple users to share server resources.

Private IaaS cloud servers and resources are dedicated to a single organisation and cannot be used by others.

Hybrid IaaS cloud provides the option to manage some physical servers in a private cloud, while outsourcing other servers to a public cloud.

In a cloud computing stack, IaaS resides on the bottom layer, PaaS delivery occurs on the middle and SaaS delivery occurs on the top. IaaS is bundled together with PaaS and SaaS delivery for a complete cloud computing solution, such as Amazon (Amazon Web Services), Google (App Engine) and Microsoft (Azure and AppFabric).

### A few examples of IaaS

Burre says, “To expedite our clients’ growth and help them realise the optimal value of their modernisation investments in IaaS, CSS Corp. built Contelli. It is an automated platform that promotes context-driven intelligence for IT operations. It involves managing applications and data in data centres, cloud and hybrid environments.

“Contelli is largely based on a customer’s business-critical metrics and more closely aligned with factors impacting business outcomes. The platform learns from new scenarios, enriching its predictive intelligence to handle issues that may arise in future. It provides three benefits on the infrastructure front: improved service agility, process efficiency and reduced overall cost of operations.”

Contelli contextually evaluates and adopts the following approaches to provide faster remediation to challenges in IT operations:

1. Reference to knowledge base: Based on the knowledge gained from historical events, Contelli helps enterprises identify early signals of system downtime through log data, and predicts future behaviour, resulting in increased operational efficiency. Through a three-pronged approach, the platform proactively identifies and classifies key incidents that lead to downtimes, failures, sub-optimal performances and outages, and provides immediate resolutions.

2. Ability to learn from new scenarios: Contelli also learns from new scenarios and understands system behaviours. The platform has built-in algorithmic scripts that can be applied to real-time scenarios to automate infrastructure completely.

In most scenarios, both levers come together to drive faster resolution and optimisation of the infrastructure ecosystem. Contelli executes

interdependency analysis between components, devices and systems for more accurate prediction. The platform can connect to multiple data sources including structured, unstructured and semi-structured data.

Vikram Puri, chief executive officer, Transworld Technologies, says, “We have created Mobile Eye, a smart Edge computing Internet of Things (IoT) device and coupled it with a complete cloud-based machine-to-machine (M2M) IoT platform called FleetView. It is the backbone of FleetView infrastructure.

“FleetView has something for each stakeholder in the supply chain, from driver behaviour and road safety right to load and route optimisation, and full compliance and audits. Drivers can keep track of their rewards and demerits. Companies can monitor safety and compliance, and manage journey risks. Supply chain professionals can plan and optimise their loads and shipments. Fleet owners can manage their cash, billing, fuel and vehicle maintenance.”

Products, including driver management centres, vehicle management services, journey risk management and route map pro, work on the capabilities provided by Mobile Eye. Mobile Eye unit comes with GPS and GSM/GPRS interface, which measures date, time, speed, latitude, longitude and distance travelled by a vehicle continuously online. Information recorded is sent to command data centres peri-
