

The Wall—the world's first modular microLED 371cm (146-inch) TV from Samsung

Siren creates neuro-fabrics, and its first product is diabetic socks that help people living with diabetes avoid amputations. Sensors are embedded seamlessly into the fabric to monitor temperature 24×7 to find foot injuries early. The socks can be washed in machine and need not be charged.

InBody 570 machine demonstrated at CES does advanced analysis of your body composition. It not only measures fat and muscle but also intracellular and extracellular water in your body. These body water values can help in identifying and tracking inflammation, swelling and even injuries by noting how these ratios change over time. You just have to stand on the machine for five minutes to get the analysis.

You are well aware of 3D printing but do you know what 2.5D printing is? Casio showcased its Mofrel 2.5D printer that uses near-IR light to form slightly raised patterns (like embossing). This sculpting technique replicates material feel that you get on touching a textured leatherite sheet for instance.

As explained by Casio, the ink used to print the bump data (for the texture) contains carbon molecules. Exposure to near-IR light causes these molecules to vibrate, causing friction and thus heat. This heat, in

turn, causes the micropowder layers to expand, thereby forming indentations on the digital sheet.

Not many in India would have heard the name of Royole Corporation. Formed in year 2012 by Stanford engineering students, it is a

leading innovator and manufacturer of next-gen products like advanced flexible displays, flexible sensors and smart devices.

Royole's flexible capacitive sensors can be curved or bent to a very small radius of 3mm to form rolled-up keyboards for example. These support multi-touch gestures and bezel-less design at lower cost than the traditional rigid sensors.

Royole's flexible displays are just 0.01mm thin with a bending radius of 1mm. These are lightweight, shatterproof and highly energy-efficient. **EFY**
