

Use location tracking selectively

Most present-day mobile applications draw a magnitude of data, including location details. This keeps the smartphone GPS system constantly active and, consequently, drains the battery. The best option is to ensure that Location feature is turned off, except when you are using a GPS-driven service on your phone. In addition, you may stop location-tracking applications from running in the background, when not in use. This ensures your processing unit gets a breather from the consistently active applications.

Use a powershare device

You may call this a cheat code to keep your phone battery running. A powershare cable like Pebble PowerShare Z can be a life saver, especially when you cannot be near a power source or are not carrying a powerbank. If someone around you can afford to share a little charge from their smartphone with yours, connect one end of the powershare device to the charging port of that device and the other end to yours to initiate the charge transfer. Keep in mind that the

phone providing the charge should be OTG-compatible. With Pebble PowerShare Z, even iPhones can be charged using the additional accessory provided in the box. These cables cost about ₹ 400.

Use voice assistant only when needed

For Android users, Google Assistant may keep running in the phone's background, and you may not even notice it. This happens when Google Assistant is in hands-free mode—always active to detect the words 'OK Google' in your voice. While it is a handy feature, you can choose to turn it off while not in use.

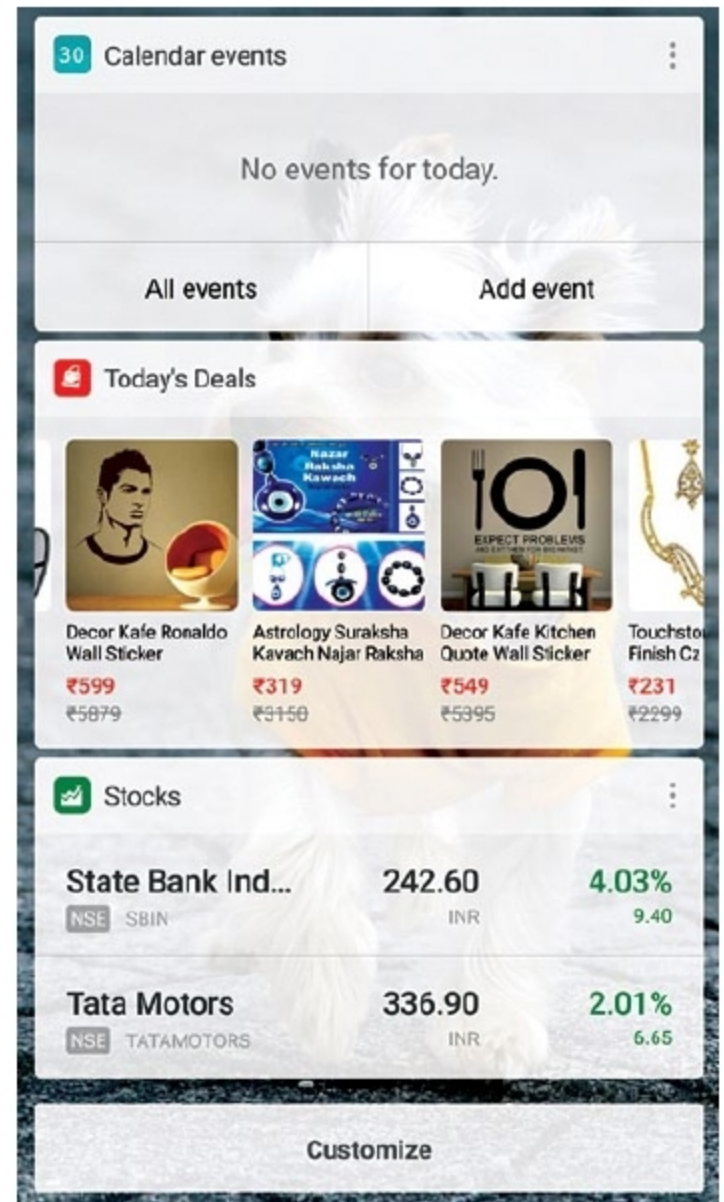

You can follow the below mentioned steps to disable Google Assistant from your Android phone.

1. Access Google Assistant settings either from Google Search app or Google Assistant App directly.

2. Go to Settings and select Phone. Inside Phone, find OK Google Detection option and turn it off. You can turn it back on whenever needed.

Update all software

Be it your phone's operating system, user interface software or installed applications, ensure all are running with their latest updated versions. Many a time, updates put emphasis on battery optimisation. Development teams fix issues or bring improvements that can stop the software from drawing any more battery than it actually needs.

Widgets drain out smartphone battery quickly

Other precautions

You can follow some other steps to further optimise your battery usage. For starters, set your brightness to auto mode, or manually set it to a position where you can read the screen under full sunlight—full brightness can flare up the display.

Ensure Bluetooth, Wi-Fi and mobile data are on only when in use. Do not allow heavy-duty applications like games and video players to run in the background.

Experts suggest that it is a good idea to charge your phone up to 95 per cent instead of fully charging or overcharging the battery. This reduces stress on the battery and ensures its long life.

Additionally, it is a good practice to use the charger provided for your phone instead of borrowing chargers that are meant for other models or brands. **EFY**
