

Making SECURITY the PRIORITY

IoT bridges the gap between the digital world and the physical world, which means that hacking into devices can have dangerous real-world consequences. As IoT applications collect more and more previously unexposed often private data, and allow access to various control functions over the internet, security becomes a major challenge.

Along with this widespread adoption, developers face new challenges to make sure that IoT applications are sufficiently secure because these applications handle a lot of sensitive data. Many security breaches have already been reported for IoT solutions, so developers must focus on building security into their IoT applications when they design and implement such solutions.

The Framework of Nebulae provides highly secure communication and scalable network with 3-tier encryption using the AES-128 bit standard. NebuLink Nodes, NebuLink Gateway and NebuLink Middleware are secured with multiple layers of encryption and TLS/ SSL security in order to prevent data tampering or unrestricted access. Application layer security is provided by DTLS, TLS over UDP.

The advanced communication feature of Nebulae Framework makes it the best choice among the IoT application developers and solution providers.

Features of Nebulae Framework Security:

- Authentication
- Secured Communication
- Secure Firmware Update
- Cryptographic Key Generation Management
- Confidential Data Storage
