This report details the nuances that go into setting up an electronic counter making business

We are surrounded by different electronic gadgets, most of which contain electronic counters. Be it for scientific purposes, domestic uses, keeping track of time or counting stocks, we require tools that help us in easing calculations. Enter electronic counters!

An electronic counter is a digital logic device that stores and displays specific events continuously, according to its configuration and programming. Sequential digital logic circuit is a common type of counter. It consists of a single input line (clock) and a number of output lines. Value of the output lines denotes a number in binary number system (BCD, or binary coded decimal).

Electronic counters can be implemented by using register-type circuits, like flip-flops. These are classified into different types, and a few of these are mentioned below.

1. Synchronous counter
2. Asynchronous counter or ripple counter
3. Up/down counter
4. Decade counter
5. Ring counter
6. Cascaded counter
7. Johnson counter
8. Modulus counter

These electronic counters include arithmetic functions, controllers, batch counters, count totalisers, event counters, pre-sets, pulse counters, delay cycles, position indicators, rate meters or tachometers, and time meters.

Reset capability of the counters can be none, manual, remote or auto reset (model dependent). Electronic counters are available in several mounting configurations, including stand-alone ones. Considering the vast operations of electronic counters, you can figure out that the scope of this business to thrive in India is huge.

Market potential

The electronic counter market in India is prominently increasing due to an increase in the usage of electronic gadgets in every aspect of life. The major factor driving the adoption of

Applications of counters

Counters have found their application in many digital electronic devices. Some of the applications are listed below.

- Frequency counters
- Digital clocks
- Analogue-to-digital convertors
- With some changes in design, counters can be used as frequency divider circuits
- Time measurement (calculating time in timers in electronic devices like ovens and washing machines)

electronic counters is the increasing demand for consumer electronic products. For example, electronic counters are used for setting AC timers, setting timers to take pictures using cameras, flashing indicator lights in vehicles and so on.

Electronic counters can also be used as clock dividers. These devices are used in businesses such as retail shops, for calculating the incoming and outgoing of customers. These are also widely used for manufacturing purposes, for controlling batch sizes, punch/drill products or cut materials. Importance of these precision instruments is enormous in business applications.

Raw materials and equipment

Electronic counters consist of many tiny electronic components. These components are made from a variety of raw materials, as given below.

Metals. Copper is often used for its excellent conductivity and malleability (the ability to be shaped and mashed). Nickel, chromium, aluminium, lead, silver and tin are also used.

Plastics and other petroleum-based materials. Plastics and petroleum-based materials are used in electronic components mostly for their insulating and heat-resistant properties.

Minerals and non-metallic materials. Silicon—considered a metalloid or semimetal—is used in microchips and semiconductors. Other non-metal or semi-metal materials are antimony, bismuth, cobalt, fluorite, garnet, magnesium and talc.

Other raw materials. Ceramics are used

Electronic counters are found in a variety of electronic devices and gadgets, including cash registers
