

AI-POWERED PLATFORMS: The Answer To India's Traffic Woes

➤ Traffic management has collateral benefits of reduced environmental pollution, improved mobility and transport systems, and an overall improved way of life for citizens

Indian cities have always faced challenges with traffic management. Especially in metros and tier-1 cities, a high number of vehicles lead to heavy traffic congestion every day. Assigned traffic officers have their hands full during busy traffic hours, leading to much difficulty in manual traffic control. Artificial intelligence (AI) can help solve these problems. AI-powered traffic control systems as a concept

have been available for a while now. However, most practical AI platforms for traffic management today are either under R&D or are on their pilot deployments.

How AI can improve traffic

The basic necessity for an AI platform to function is data feed. An intelligent traffic system requires deployment of several sensors, radars, microprocessors, imaging systems and more,

which can capture traffic data in real time and provide it to the central AI platform. The platform, in turn, creates analytics surrounding various parameters, providing insights that can be used to predict traffic behaviour and strategise traffic operations.

Further, AI platforms may be driven by neural network-powered deep learning engines that, by analysing all real-time as well as historical data, understand patterns and control
