

all blocks are not allowed to enter the network without proper validation; a block can only be added with a proper validator's signature. Once the block enters the network, it becomes persistent with no reverts.

HydraChain platform provides the following components in a blockchain:

- Transaction cost, which is the cost of executing computational steps in a transaction. In HydraChain, cost is calculated on the basis of requirements.
- Gas limits, which are basic units for transactions executed in blockchain. Every transaction is sub-divided into opcode, and every opcode has specific gas units based on opcode type.
- Genesis allocation, which is related to the hashing and mining capacity of blockchain.
- Block time, which is the time delay between mining or validation of two blocks.

MultiChain. MultiChain is an open source blockchain platform

that enables user-based networks to supposedly perform 1000 financial transactions per second. It enables enterprises to build and implement blockchain applications with speed. It is specially designed for customers with requirements similar to what Bitcoin offers but with special features for corporate entities.

With MultiChain, banks can build their own blockchains. It offers users 45 customisable parameters and changeable protocol-level restrictions.

Following are some unique features of MultiChain:

- 1000 transactions per second
- Dynamic control over connections, send and receive transactions, asset creation, streams and blocks
- Cross-chain applications and users can issue millions of assets on blockchain
- Highly developer-friendly and fully customisable
- Extends Bitcoin protocol, formats and APIs including full multi-signature support
- Ideal for data sharing, encryption

archiving and time stamping

Latest version: 1.0.4

Openchain. Openchain, a distributed ledger based on open source technology, is specially designed for organisations to issue and manage digital assets in a highly scalable, secured and robust manner. Openchain does not make use of the concept of blocks—transactions are directly chained to one another. Transactions get linked to the chain at the same time that these are submitted to the network.

This is how it works:

- There is a single authority for validating transactions for every Openchain instance.
- Rather than having one single central ledger, every organisation has complete control over its respective instance and every instance connects with each other.
- Different transactions are validated by different authorities, depending on the exchange of assets.
