

AI For Mission-Critical Applications: It's All About Smarter Decisions And End Results

Artificial intelligence (AI) technology is employed in safety-critical situations such as airports, ATM machines and aircraft operations. When decision-makers and business executives have reliable data analyses, recommendations and follow-ups through AI systems, they can make smarter decisions and better choices for their business, employees and future actions

Show a photo of a dog to a three-year-old child, and she or he will be able to tell you it is a dog, and that may not be considered remarkable. But if a machine can tell you the same thing, it would be considered remarkable. This is because for a machine to achieve that feat would require a form of artificial intelligence (AI) development called deep learning. The machine has to be trained using thousands of dog images, otherwise it will merely perceive it as a blob and give an incorrect answer. In the above example, unlike the machine, the child can learn things intuitively and unsupervised, and it comes as no surprise when she or he can easily recognise the animal.

Not Hotdog app seems farcical and

absurd, but it has a very interesting factual and practical aspect to it. This app is based on cutting-edge AI and computer vision technologies that can identify a hotdog from other food items or objects. It was developed for fun and experimentation. But with advancements in modern technology, we can use AI algorithms to easily identify animals, objects, places and people for use in critical applications.

It is easy to build an AI app like Not Hotdog for fun and experimentation, but what does it take to build a mission-critical AI application that you can trust to help run a business or accomplish a task successfully? Let us take a look at a few cases of AI in mission-critical applications in this article.

If Not Hotdog app does not give a correct
