

T&M Criteria And Requirement For The INDUSTRIAL IoT

Combining new technology with rapidly-developed software on newly-created hardware—where critical bugs concerning reliability, safety and performance are often overlooked—makes testing of Industrial Internet of Things (IIoT) devices difficult. However, advancements in technologies are making industries more effective and enabling machines to work smartly

The time is not far when the IoT will become essential for testers to survive in the development world. The IoT-enabled gadgets, smart device applications and communication modules play a vital role in evaluating the performance of various IoT services. As IoT technology evolves, there is a need for testing at different levels, namely, chipset, module and end host device. The IIoT monitors, collects, exchanges and analyses information to enable machines to change their own behaviour, or instruct other devices to do so, without human intervention.

IIoT testing depends on the sensitivity of devices (as specifications change from

vendor to vendor), reliability of network and so on. Users' security and performance concerns can be dealt with successfully by vendors, encouraging the use of such devices around the globe.

Need for IIoT test and measurement

IIoT testing is based on the system involved. Testers should concentrate on test-as-a-user approach rather than testing based on requirements. It is necessary to certify a complicated mesh of devices, protocols, hardware, operation systems, firmware and so on.
