

Testing And Monitoring Of FIBRE-OPTIC NETWORKS

An optical network monitoring system accurately detects and locates fibre degradation, alerting operators and managers with the details of faults. Measurement at desired intervals allows network operators to assess long-term fibre performance and efficient asset management

EFY BUREAU

Transmission of radio frequency (RF) or direct current (DC) over optical-fibre offers immunity to electrical interference. A fibre-optic network test involves optical channel monitoring, bit error rate testing, protocol testing, signal loss determination and other aspects of network deployment and service assurance. Optical time-domain reflectometers (OTDRs), bit error rate testers, optical spec-

trum analysers and optical power meters are some of the commonly-used tools.

Testing is done to evaluate the performance of fibre-optic components, cables and systems. Components such as fibres, splices, connectors, LED or laser sources, detectors and receivers are being developed to test and confirm performance specifications. Designers of fibre-optic cable plants and networks depend on these specifica-
