

Adaptive traffic-control system (Credit: <http://itsslabs.com>)

in-vehicle terminal communicates with the traffic control centre and the traffic information service centre respectively via the cellular mobile communication system (satellites or telecom towers).

The traffic-control centre provides real-time data related to traffic density in each lane to the priority algorithm controller, which is embedded in the smart box connected to traffic lights. The controller processes the data and transmits controlling signals to the smart traffic lights for switching the traffic lights based on traffic density in each lane. Data collected by the traffic-control centre assists law-enforcing agencies by providing real-time information as soon as a stolen vehicle is detected, monitoring carbon emission by vehicles by synchronising to the database of pollution checking central office, providing automatic and real-time information of any accident taking place on highways, integrating an automated digitised system for detecting traffic violations and issuing an online e-challan to vehicle owners, and providing a clear road for smooth movement of traffic during emergency situations.

ITMS in India

India has started taking steps in planning and initiating ITMS in metro cities, to start with. Delhi Police is currently working on a ₹ 820-million ITMS project, which covers 220 kilometres of urban roads with 240 signal intersections.

To help improve traffic manage-

ment a scheme has been implemented in Bengaluru. It is running from a dedicated traffic-management centre from where a team remotely manages the city's traffic. Nearly 120 cameras at different junctions are remotely monitored. Out of 300 traffic signals, 163 have been connected to the traffic-management centre, most of

which are vehicle-activated. This means, if there is a four-second period where no vehicles pass through, the signal automatically turns to red. As part of Mumbai City Mobility Management project, nearly 700 vehicle-presence-intelligent camera detectors and in-road magnetic loop detectors are under installation at various busy road junctions controlled by traffic signals. Based on the information received from these cameras and in-road magnetic loop detectors, an adaptive traffic-control system alters traffic signal cycles in real time to respond to changing traffic conditions. Once fully-operational, ATCS is expected to cut down waiting time at traffic signals by almost half.

In Chennai, integrated video sensor technology is under trial for intelligent traffic management. One hundred traffic camera sensors have been installed and are operational to detect waiting vehicles at multiple intersections across the city.

Karnataka State Road Transport Corp. is planning to soon implement ITMS for Mysore city under an initiative by World Bank. The scope of implementation consists of design, development, testing, installation, commissioning, training, operations and management of facilities for a period of three years. The project covers 500 buses, 80 bus stops and 10 bus terminals. It will have a vehicle-tracking system, central control station, passenger

MECO
SINCE 1962

LEAKAGE CURRENT TESTER

Applications / Usage

- AC Leakage Current of Earth / Ground
- Out of Balance Leakage Current
- AC Load Current
- Relay Output in Protection Panel
- Utilities, Oil Fields & Plants
- Processing & Automation Industries
- Building Management System

Features

- 10mA Ultra High Resolution
- Large Conductor Diameter (30mm)
- AC Current in 4 Ranges (20mA, 200mA, 2A, 60A)
- Wide Frequency Response (40Hz~400Hz)
- AC A, AC V, DC V

Meco Meters Private Limited

Plot No. EL-60, MIDC Electronic Zone,
TTC Industrial Area, Mahape,
Navi Mumbai - 400710 (INDIA)
