

pattern, defective pixel, uniformity, colour distance, gradient, sharpness, viewing angle, gamma and response time.

Various test scenarios depend on the monitor, what it can handle to a greater or lesser extent. For example, a graphics monitor impresses with a particularly homogenous image display and smooth gradients, whereas a gaming monitor is distinguished by particularly short response times. This helps assess a monitor within the context of its respective device category.

Near-eye display

system. Gamma Scientific's GS-1290 provides the test capability for a wide variety of parameters including contrast, luminance, pixel/line defect, image distortion, colour uniformity, image virtual distance, field-of-view, response time and resolution. It deliv-

ers high spatial resolution display quality measurements for virtual reality (VR), augmented reality (AR), mixed reality and head-up displays. Its fully-automated robotic system allows for millisecond measurement times with superior wavelength and

colour accuracy from as low as 250nm all the way to 900nm.

Uniformity testing for backlight unit (BLU). Light leakage and non-uniformity in LCD and LED BLUs can render the performance of a display unit. To ensure that every BLU meets performance standards, Radiant's TrueTest software comes with a library of predefined tests. It includes brightness and colour uniformity testing with chromaticity and contrast in panel display inspection. It provides high-speed, automated inspection for quality control on the production line to high-

precision solutions for R&D.

Detection of foreign material. For suppliers of glass, film and other sub-assemblies, imaging colorimeters provide early identification of defects, reducing overall production costs by
