

How Technology Can Help In Waste Management

Such technologies as artificial intelligence, Big Data, machine learning and robotics, if implemented properly, can make the Indian waste management sector much more efficient

Vinayak Ramachandra Adkoli is BE in industrial production. He has been a lecturer in mechanical department for ten years, in three different polytechnics. He is also a freelance writer and cartoonist

Waste management is the generation, prevention, monitoring, treatment, handling, reuse, etc of solid waste. There are various types of solid waste including municipal, agricultural, hazardous, household and so on.

Waste is created by various human activities, and recycling processes are generally undertaken to reduce its effects on health, the environment or aesthetics. In 1971, the first municipal waste management effort was carried out in North America.

India produces 62 million tonnes of solid waste per year, but only 75 to 80 per

cent of that waste gets collected and 22 to 28 per cent is processed and treated, according to Ministry of Environment, Forests and Climate change.

Rapid industrialisation and population explosion in India have led to the migration of people from villages to cities. This generates thousands of tonnes of municipal solid waste (MSW). MSW is expected to increase significantly in the near future.

Automation and waste management

In critical areas like solid waste management, electronics and automation sectors
