supports many new devices. The device manager sandbox uses an application programming interface that adds high-level functions to interconnected devices. The subroutine call protocol is an upgrade in Zerynth advanced device manager that helps in taking service from a system without having the details

of any remote system. The Zerynth advanced device manager can also be connected easily with the cloud monitoring the IoT services.

Also, in version 2.0.5, the Zerynth App and its library have been clubbed with Zerynth advanced device manager. The refreshed Zerynth App includes push

notifications and enhanced graphical user interface.

New hardware supported by Zerynth 2.0.5 include WeMos D1 Mini, SparkFun RedBoard and Atmel SAM D21 xPlained PRO. While SparkFun Photon is a Wi-Fi enabled development platform, WeMos D1 Mini is a small Wi-Fi device for prototyping small smart objects linked to the web. On the other hand, xPlained D21 is an Atmel microcontroller-based device with some upgrades in the board for development of customised designs.

Zerynth and smart world

Zerynth IDE is easy to handle. It allows you to use any 32-bit microcontroller to design any embedded application for the IoT. It can connect to any cloud infrastructure. So, to create a system on cloud, there is no need to cut, copy, paste or drag from different sources now. **EFY**
