

Electronics Projects Vol. 26 is the latest volume in the series, available in digital form.

It is a compilation of
**21 construction projects and
71 circuit ideas published in
Electronics For You magazine.**

This collection of tested circuit ideas and construction projects in a handy volume would interest all classes of electronics enthusiasts—be they students, teachers, hobbyists or professionals!

Electronics Projects Vol. 26 is available on the following digital magazine stores:

- www.lulu.com
- www.magzter.com
- Createspace.com
- www.readwhere.com

COMPUTING

Serverless technologies

out worrying about provisioning, managing or scaling the underlying infrastructure—just put your code in the cloud and run it! Keep in mind that this applies to platform-as-a-service (PaaS) as well. Although you may not deal with direct VMs with PaaS, you still have to deal with instance sizes and capacity.

Think of serverless as a piece of functionality to run; this functionality is not run in your machine but is executed remotely. Typically, serverless functions are executed through an event-driven fashion—as response to events or requests on HTTP, the functions get executed. In case of the MovieBot, Lambda functions are involved to serve user queries as and when users interact with it.

Use cases

With serverless approach, developers can deploy certain types of solutions at scale with cost-effectiveness. We have already discussed chatbots, which is a classic use case for serverless. Other key use cases for serverless approach are:

1. 3-tier web applications. Conventional Single Page Applications (SPA), which relied on REpresentative State Transfer (REST) based services to perform a given functionality, could be re-written to leverage serverless functions front-ended by an API gateway. This is a powerful pattern that helps your application scale indefinitely without concerns of configuring scale-out or infrastructure resources.

2. Scalable batch jobs. Batch jobs were traditionally run as daemons or background processes on dedicated VMs. More often than not, this approach hit scalability and had reliability issues—developers would leave their critical processes with single points of failure. With serverless approach, batch jobs can now be redesigned as a chain of mappers and reducers, each running as independent functions. Such mappers and reducers would share a common data store, something like a blob storage or a queue, and they can individually scale up to meet the data processing needs.

3. Stream processing. Related to scalable batch
