the path for direct user contributions—as described in the Design for Manufacture article being carried elsewhere in this issue, where a small change in Valor tool is done universally without messing up with the perfection of the tool.

No more bugs. Earlier, bugs in the complex PCB traces used to mess up with other existing tracks in the layout, making it difficult for the designer to find errors in the circuit. The software supports high-DPI display, making it easy to see.

Self-handling of customised tools. Earlier, customised parts used to be stored in a hidden location, which made it difficult for designers to edit them with an external tool. But now, these parts can be conveniently located in the /Documents/ Fritzing folder, making the work much easier for users.

Load or save uncompressed Fritzing file. Designers can now use an uncompressed set of compatible files like git or SVN. New file types and shiny icons suitable for MAC OS X platforms have been released in the market.

Fritzing is compatible with MAC OS X, Windows and Linux platforms. The source code of Fritzing is written in C++ language. It is available in both 32-bit and 64-bit Linux packages.

As with Pad2Pad, users can order the PCB to manufacture on Fritzing Fab itself. This saves them time and money on developer boards from other manufacturers.

Goals of Fritzing

There are various licensed and open source design and simulation tools available for PCBs. A complete solution that provides design, simulation and manufacturing is a lucrative offer for designers. Above all, they can visualise their circuits and errors, and rectify simultaneously to validate the design. It is like a box of wonders, which makes the life of designers much easier. **EFY**
