times to remove transients. The lesser the transients, the greater the efficiency and perfection in the design.

Also, feedback increases the efficiency through continuous improvements in input and output techniques. These

additions to SU2 software help to fix bug issues and improve the system's stability. Besides, boundary conditions help achieve accuracy.

Algebraic transition model implementation. Aircrafts are streamlined in order to handle turbulence. Hence this transition can be well calculated using algebraic transition model. From wheel rotation to turbine movement to wing movement, everything can be monitored. And SU2 does it perfectly.

The SU2 boon

SU2 is developed to enhance the stability and efficiency of aircrafts. The fluid mechanism and dynamics is itself a wide area that needs to be explored more on mathematical concepts and design basics, thus creating a constant demand for simulation software such as SU2. **EFY**
