

Electronics Projects Vol. 26 is the latest volume in the series, available in digital form.

It is a compilation of **21 construction projects** and **71 circuit ideas** published in **Electronics For You** magazine.

This collection of tested circuit ideas and construction projects in a handy volume would interest all classes of electronics enthusiasts—be they students, teachers, hobbyists or professionals!

Electronics Projects Vol. 26 is available on the following digital magazine stores:

- www.lulu.com
- www.magzter.com
- Createspace.com
- www.readwhere.com

make a decision that is better than CNN's. Even if an autonomous vehicle system could be programmed to determine which path the vehicle should take in any given scenario, extensive testing would be necessary to provide evidence that autonomous vehicles are, in fact, safer than human drivers.

A common misconception is that autonomous vehicles will provide a safer, crash-free future for transportation. While this is the main goal of autonomous transportation, statistics are yet to support this claim. Although computerised systems can compensate for human errors such as emotional distractions and insufficient reaction times, collisions cannot yet be completely avoided.

There are some factors that a computer cannot predict in a crash situation. In a potential crash situation, the CNN is responsible for making two decisions: whether a collision is going to occur on the vehicle's current path, and if so, which new path to take. According to mileage data collected in 2009, a CNN controlled vehicle would have to drive 1,166,774km (725,000 miles) without human intervention to maintain a 99 per cent confidence that it can drive more safely than a human driver. While there have been many advances in autonomous vehicle technology, more testing is needed before it will create a legitimately safer driving environment.

CNN technology enablers

OpenVX. The Khronos Group is working on an extension that will enable CNN topologies to be represented as OpenVX graphs mixed with traditional vision functions. OpenVX is an open, royalty-free standard for cross-platform acceleration of computer-vision applications. It enables performance- and power-optimised computer-vision processing, which is especially important in embedded and real-time use-cases such as face, body and gesture tracking, smart video surveillance, advanced driver assistance systems (ADAS), object and scene reconstruction, augmented reality, visual inspection and robotics.

OpenVX is a low-level programming framework domain that enables software developers to efficiently access computer-vision hardware acceleration with both functional and performance portability. It has been designed to support modern hardware architectures, such as mobile and embedded SoCs as well as desktop systems. Many of these systems are parallel and heterogeneous, containing multiple processor types including multi-core CPUs, DSP subsystems, GPUs, dedicated vision computing fabrics as well as hardwired functionality.
