

Dynamo fleet

Dynamo 1T

ultimately determine the throughput of any system, which is controlled by the software. Our modular nature of software allows easy customisation and addition of new features as per business requirements, which is not possible with other players.

What types of conventional automation solutions do you offer and what percentage of your revenue comes from these?

In the current context, intra-logistics automation predominantly belongs to conventional automation systems, which are generally known as fixed automation systems. It includes automation which is fixed in nature and carries out repetitive, fixed processes to reach high-volume production and storage goals. It can operate at predefined throughput numbers, and enhancing throughput

means building new infrastructure. But with our deep technical insights and capabilities, we can provide enhanced efficiency in the existing space. We offer solutions such as shuttle based ASRS for pallet and carton movements, crane based ASRS, smart conveyors, and other semi-automated picking technologies which support the conventional automation system. Today, more than 50% of our revenue comes from solutions focused on conventional or fixed automation.

What types of robots are you manufacturing at Bot-Valley right now? What is your manufacturing capacity?

Right now, we are producing mobile robots. These robots can be used to transport different materials from one location to another. There are three different families of mobile robots that we manufacture.

Decimator

One is Dynamo, which caters to the 50kg to 1,500kg payload. I call them equivalent to self-driving cars as these come featuring the same kind of sensors and software you will find in self-driving cars. These are almost as intelligent as human beings. The second is the Zippy range of robots, which are mostly used in sorting and transportation applications. These use QR codes pasted on the floor and follow the travel path accordingly. The third is the Veloce range of robots, which are among the most intelligent robots that we have developed at Addverb.

Our manufacturing capability lies in the range of 10,000 to 50,000 robots per year. This varies depending on the kind of robots that we are manufacturing. We will be launching our first range of cobots in the month of June or July this year. The R&D around the same is going on and we have all the joints ready.

What's the story behind naming the facility Bot-Valley?

The name Bot-Valley originates from our customers who visit the facility. Most of these people who visit our new facility in Noida say that the same is not a factory. The team at Addverb also did not want the same to be referred to as a factory and hence came the name Bot-Valley. The fact that we bring robots alive here for the world, and our aim is to put India on the map of robotics manufacturing using this facility, has also contributed to the name. We try to ensure that every article or news about us carries the name Bot-Valley. We are proud of the fact that there exists a Bot-Valley in our own India! **EFY**
