

Last Mile Electric Mobility In The Midst of Disruption

Dr Amitabh Saran

World is on the path of energy transition in mobility sector. The adoption of electric vehicles (EVs) is constantly rising. Since the past couple of years, we have been observing a shift towards electric mobility (eMobility). This shift towards EVs is primarily due to their ability to reduce pollution.

Data suggests that around 1.2 million people die prematurely in India due to outdoor air pollution, and road transport represents 25% share in air pollution, including greenhouse gases. The air pollu-

tion impacts our GDP by 3%. These figures are when we have approximately 30 million three- and four-wheeled fossil-fuel vehicles in India, and we can expect a lot more as the disposable incomes are increasing. India has only 22 cars per 1000 individuals, and the number will rise exponentially. Therefore, there is a need for a disruptive innovation and increase in the adoption of EVs.

The sale of EVs is growing year-to-year as government regulations try to reduce pollution by increasing the adoption of EVs. But why electric and not other fuels like CNG,
