

and monetising content.

You can head to CES website and official YouTube channel to check out snapshots of the exhibitions, and discussions that happened in the backdrop of CES 2023, such as how to build a business in the metaverse, bringing a heritage brand into Web3, and more.

Showcased at CES

There were a lot of exciting metaverse-related products on display at CES this year. bHaptics showcased a full body haptic suit, with accessories spanning from head to toe. It lets users feel more than 300 experiences—from handshakes and hugs to raindrops and explosions. They aim to connect people with the digital world in more natural ways.

At CES, Ixana unveiled a new ultra-low-power chip, which is based on a disruptive wireless tech called Wi-R, and provides smart devices with the ability to securely communicate with touch. Wi-R is a ‘wire-like wireless technology’ developed at Purdue University for body area network devices. It uses the electro-quasistatic field around you for private, high-speed, ultra-low energy data transfer.

This combines the security and performance of wires with the convenience of wireless communication. “Compared to Bluetooth, Wi-R offers 100X better energy efficiency,” said Shreyas Sen, Chief Technology Officer of Ixana, in a statement. “Additionally, Wi-R boasts faster data rates, lower latency, and higher reliability with its interference robustness and low bit error rates. Wi-R is confined near the surface, which leads to unique advantages in physical security, multi-node co-existence, touch detection, and communication.”

When using this technology, wearable devices like headsets will not need their own processors or bulky power sources, making them

light and comfortable enough to use all day long. “Ixana will do for wearables and the metaverse what Qualcomm did for mobile phones—introduce transformative capabilities with high-speed data and distributed computing, leading to accelerated adoption,” added Angik Sarkar, Chief Executive Officer, Ixana. The evaluation kit is now available for pre-order. Ixana expects this tech to find its way into devices in around 2-3 years.

Magic Leap showcased eight AR solutions built on Magic Leap 2, an immersive enterprise AR device. These included Cisco’s Webex Hologram, an immersive 3D meetings solution; NVIDIA Omniverse, a digital twin solution for industries; Taqtile Manifest, an AR-enabled platform for deskless employees to successfully perform complex operational and maintenance tasks anywhere and at any time; Geopogo, an immersive, multi-user visualisation app that lets users instantly convert their 3D design files into AR models; Avrio, an immersive and customisable AR training software platform for defence and public sector personnel; and Brainlab, which lets medical professionals view diagnostic images in 3D.

Magic Leap Assist lets users share their on-device view of real-world and digital content with experts, to get in-context assistance. Magic Leap Wildfire, which was developed by Magic Leap for the World Economic Forum, is a defence and public sector command and control station demonstration.

HyperVSN’s SmartV holographic solutions also garnered a lot of attention at CES, as no one could ignore a 4.9-metre (16ft) tall holographic human talking or performing in front of them! Using a set-up that included the SmartV Wall, SmartV Digital Avatar, and SmartV 3D Modeller solutions, HyperVSN demonstrated holographic livestreams and futuristic retail solutions. Their holographic displays work both indoor and outdoor. You can livestream a performance by an actual person. Or, you can create a hologram of a completely artificial intelligence (AI)-driven avatar, say, to respond to customer queries in a retail store.

TCL showcased what it claims to be the world’s first AR glasses. It looked pretty much like normal glasses, and people wearing it seemed to be at ease. The AR glasses can auto-translate when
