

IMPLANTABLE CHIPS: Animal Identification And Data Tracking Device

ASHWINI KUMAR SINHA

In zoos, prisons, animal-based parks, and pet houses with snake breeding tanks, efficient tracking and management are imperative. Visual identification by human eyes is often impractical due to the similar appearances of animals. AI image processing is also challenging due to their identical looks. Therefore, the need arises for an implantable tracking system involving chips to facilitate identification and data retrieval, including health conditions, age, species type, origin, and other relevant information.

This system can prove invaluable for IoT-based animal data analysis and autonomous tracking in large national parks, forests, and zoos, aiding in monitoring the habitat of endangered species. It utilises a 125Hz implantable RFID chip, which can be easily implant-
