

5G CONNECTIVITY For Motorsports

The article explores the feasibility and design considerations for providing 5G connectivity for motorsports

There has been interest in the motorsports industry to provide 5G connectivity for the cars on track. Typically, the cars use legacy technologies like Wi-Fi or digital video broadcast (DVB) to provide the connectivity for backhauling telemetry, video, and audio data from the cars back to the pit and media centre for broadcasting. However, the current solutions provide a limited bandwidth, and throughput is in the range of 10 to 12Mbps. This throughput is insufficient for advanced

use cases and capabilities like 4K streaming, 360-degree video, and telemetry for the racing cars.

The automotive industry is also moving towards a software defined vehicle (SDV) strategy, where the cars will need a highly reliable and low latency connectivity for frequent updates to the software, and to push gigabytes of data from the hundreds of different sensors on the cars. The move to electrification and softwareisation also needs a connectivity solution that is future-proof and ready for these
