

ARTIFICIAL PLANT WATER SHOWERS To Beat The Heat!

DR GEETALI SAHA AND URMIL PRAJAPATI

Considering the geographical location, some regions experienced temperatures rising to 48°C during the peak summer season. In such situations, a hydroponic structure, a water-based artificial farming setup that can be used mostly indoors, becomes essential for growing various crops. However, a question arises: Is it possible to utilise the water used in hydroponics for an afternoon water shower, scheduling it with the help of the Network Time Protocol (NTP)—an internet protocol used to synchronise computer clock time sources in a network—without any human intervention? Additionally, can we power the fogger setup to reach all the plants in the hydroponics system?

The base setup for this project is located in room D204 of the Institute, with an approximate dimension of 9.3 square metres (100 square feet). The room is non-air-conditioned and does not receive direct sunlight. The proposed setup aims to test the feasibility of using a 4-way fogger system with the assistance of NTP. We have also implemented
