

“MACHINE VISION For Object Manipulation Had To Be TREATED DIFFERENTLY”

When we look at an object, our brain immediately knows how to pick it up—whether to use a hand, or just fingers, or both the hands! This sort of intelligence is lacking in current robotic systems. CynLr, a Bengaluru based robotics deep-tech startup, is now solving this problem using a unique approach.

In an interview with EFY, Gokul N.A. and Nikhil Ramaswamy, Co-founders of CynLr, talk about how they are working towards achieving such visual object intelligence for industrial robots

We understand CynLr stands for Cybernetics Laboratory. Could you please explain to us the significance of this name?

Gokul: Cybernetics is a counterthesis to typical AI and blackbox ML approaches. AI is a very collec-

tive term, and there are different structures to it. We usually treat AI like it is a black box—we think that there is some monolithic block of intelligence—say our brain, which we assume to be made of very similar neurons being put together

in a sophisticated way. If you feed inputs to this brain, we assume that it automatically trains to create a ‘template of the input’ in order to give the output. When we go behind template training, we do so with an assumption that intelligent systems/
