only detect paranormal phenomena, these are capable of recording voices of spirits, of the past and even registering images of auras, spirits, the dead, etc. The first scientist to study and discover the phenomenon called instrumental trans-communication was Swedish researcher Friedrich Jungerson. He recorded voices that were speaking in an extinct language. With that, he unchained a true legion whose purpose was to record the silence or white noise to find voices or even achieve communication with the beyond.

EMF meters. Electromagnetic interference (EMI) is the ability or side-effect of any object or radiation that may be a supernatural entity's presence, which can cause nearby electronics to malfunction. EMF meters measure electromagnetic radiation that originates from various sources including the Earth, people and electronics. These are calibrated to measure noticeable changes in EM radiation to detect radiation from unidentified sources at different frequencies all over the EM radiation spectrum. High levels of radiation as well as their movement in the area can be documented to investigate further.

RF detectors. It has been found through experiments by many researchers that paranormal occupancy is strongly accompanied by RF disturbances ranging from a few hertz to many kilohertz. A simple yet super-sensitive paranormal activity recording circuit can be designed, which can be used for detecting sensitive paranormal existence within a range of ten metres. Many such circuits can be built and placed at definite intervals for securing a large area. Each circuit incorporates an alarm at output, which sounds immediately on detecting a paranormal intrusion, and is ideally suitable for areas prone to paranormal activity.

Investigation progress

Since the 1920s, when Thomas Edison hinted that he might have attempted to build a ghost machine to communicate with the dead, others have tried to apply a scientific method to prove the existence of life after death. However, so far, such attempts have

not met with any success. Till date, all groups (amateur and professional) involved in paranormal investigations have their own set of protocols regarding paranormal existence and investigations.

Majority of paranormal investigators—at least the ones experienced enough to realise that most alleged supernatural events can be attributed to environmental conditions—do not simply hunt down disembodied spirits but use technology to measure as many environmental factors as possible at a given site and look for clues that suggest the perception of a paranormal event as the result of some naturally-occurring factors. Only after ruling out those natural factors can an investigator consider the possibility that a case may be supernatural.

Investigators need to improvise with technology tools as till today there are no equipment that can actually detect paranormal activity—these can only collect data. They can use such instruments as environmental sensors, cameras and recorders to monitor the environment and notice anomalies. If there is a correspondence in anomalies or data with other information, such as personal experiences, it means they might be experiencing paranormal activity.

Many paranormal investigators have built and used various electronic devices like digital video cameras (blimp cams), sensors and voice recorders for investigating paranormal events. So far, they may not have been able to get anything really substantial as far as ghosts and spirits are concerned, but such valuable electronic devices can prove to be a stepping-stone for future investigations.

Future generation of electronics instrumentation will be a mixture of electronic and supernatural forces. In future, possible use of EM waves (from very-low to very-high frequency range) in the EM radiation spectrum will allow supernatural forces to travel through optical fibres, coaxial cables used in TVs, and electrical and phone lines, which will make it easier to understand paranormal occurrences and then to sense, image and even talk to them. **EFY**
