

A Concept Of Green Cars With Futuristic Designs

Application of new materials, lightweight structures, vehicle safety and environmental regulations, hybrid vehicles, such energy systems as fuel cells, intelligent control systems, telematics, human-machine interactions, global manufacturing logistics and so on are changing the automotive industry into a complex interdisciplinary system

V.P. Sampath
is a senior member of IEEE and also a member of Institution of Engineers Ltd. Presently, he is patron of Semiconductor Federation of India

The concept of green cars and other advanced technology vehicles are a means to reduce India's dependence on imported fuel, uplift the economy and improve emissions. Green cars have been designed to objectively identify, organise and comprehend information and opinions on battery-run cars. Currently, various concepts specific to electric driving are being developed. India can only become a leader in electric mobility if battery vehicle systems can be produced domestically.

A battery electric vehicle (BEV) is powered by electricity stored in large batteries within the vehicle. The batteries are

used to power the electric motor that drives the vehicle. The electric car's navigation computer can show the driver, at the touch of a button, the driving radius within range under current battery charge, and the system can also calculate if current destination is within that range.

Most BEVs use regenerative braking, which allows the electric motor to act as a generator to re-capture energy that would normally be lost through heat dissipation and frictional losses. This, in turn, improves energy efficiency and reduces brake wear-and-tear.

BEVs benefit from high levels of torque found in electrical motors as well as smooth
