

## NASA teams up with Nokia to bring 4G LTE on Moon

NASA is planning to take a walk on the moon sometime in 2020, and it might just take Nokia's help to communicate up

Representational Image

there. In a fresh new release, the firm has said that it will be offering Nokia a funding of 14.1 million dollars to build a 4G LTE network that could work up there.

As per NASA associate administrator James Reuter, the 4G LTE network can help them communicate between lunar habitats and the astronauts when exploring the Moon's surface. "With NASA funding, Nokia will look at how terrestrial technology could be modified for the lunar environment to support reliable, high-rate communications," he said. In addition, this could also help the agency to communicate with the spacecraft.

It is worth adding that Nokia is not trying to bring 4G LTE to the Moon for the first time. The company has previously joined hands with Vodafone to build a Moon-based LTE network for the Apollo 17 landing. The network could send high-definition video from the Moon to Earth.

## 3D-printed 'invisible' fibres can sense breath, sound, and biological cells

From capturing your breath to guiding biological cell movements, 3D printing of tiny, transparent conducting fibres could be used to make devices that can 'smell, hear and touch'—making it particularly useful for health monitoring, the Internet of Things (IoT), and biosensing applications.

Researchers from the University of Cambridge used 3D printing techniques to make electronic fibres, each 100 times thinner than a human hair, creating sensors beyond the capabilities of conventional film-based devices.

The fibre printing technique, reported in the journal Sci-

ence Advances, can be used to make non-contact, wearable, and portable respiratory sensors. These printed sensors are low-cost and can be attached to a mobile phone to collect breath pattern information, sound, and images at the same time.

In addition to the respiratory sensors, the printing technique can also be used to make biocompatible fibres of a similar dimension to biological cells, which enables them to guide cell movements and 'feel' this dynamic process as electrical signals.

## Indian firms report jump in cyber threats while WFH

Representational Image

Even as Indian companies are adapting to a new normal of working from home, cybercriminals have stepped up their activities to take advantage of the situation. A new Cisco report corroborates the recent trend of growing cybercrimes targeting such organisations.

According to Cisco's Future of Secure Remote Work report, 73 per cent of organisations in India have experienced a 25 per cent or more jump in either cyber threats or alerts since the outbreak of Covid-19. It also points out that many Indian firms were caught unprepared to make the needed transition to a remote workforce. About 65 per cent of organisations had to implement cybersecurity measures to support remote working.

Other top concerns raised by organisations included data privacy (66 per cent) and protection against malware (62 per cent). The report predicts a hybrid workplace model in the future—wherein employees shuffle between remote working and in the office.
