

to begin automatically applying age-restrictions on content that may not be appropriate for audiences under 18. There are no major changes to the policy and as always, creators can appeal these age-restrictions,” the tech giant explained on its support page.

This decision is being rolled out as YouTube tries to deal with global criticism from parents and advocacy groups about the platform being unsafe for children. The platform routinely states that it is not meant for users who

are younger than thirteen years due to federal privacy protections, and YouTube Kids is the safer alternative, but that does not stop kids from using the app. Also, some of the channels on the main app are built around creating content, especially for kids.

YouTube says that this is going to be a one-time process, and they will be deleting the information once it has been verified. This process has been built to stick to Google’s privacy and security principles.

Engineers imitate human hands to make better sensors

An international research team has developed ‘electronic skin’ sensors capable of mimicking the dynamic process of human motion. This work could help severely injured people, such as soldiers, regain the ability to control their movements as well

as contribute to the development of smart robotics, according to Huanyu Larry Cheng, Dorothy Quiggle Early Career Professor in the Penn State Department of Engineering Science and Mechanics.

Cheng and collaborating researchers based in China published their work in a recent issue of *Nano Energy*.

The dual-mode sensor measures both the magnitude and loads of movement, such as the effort of swinging a tennis racquet as well as rate, duration, and direction. The trick is to decouple this measurement and understand how the separate parameters influence each other.

For example, bouncing a tennis ball gently on a racquet requires different input than serving a ball to an opponent. Those same variables come into play when a person with a prosthetic arm needs to differentiate between handling an egg and carrying a watermelon.

“We can apply these sensors to help people capture the magnitude for pressing, bending, and more,” says Cheng. “We can also use these sensors on soft robotics to manipulate delicate objects like catching a fish, or even in a disaster when they may need to crawl into irregular spaces and move debris,” he adds.

This robot helps Covid-19 patients to speak to their loved ones

A hospital in India has deployed a customer-service robot to patrol its wards, connecting coronavirus patients to friends and relatives. Its piercing eyes are equipped with facial recognition technology to help it recall people it has previously interacted with. A tablet attached to Mitra’s chest allows patients to see loved ones, as well as medical staff unable to access the wards.

“It takes a lot of time to recover, and during this time, when patients need their families the most, they are unable to visit,” says Dr Arun Lakhanpal, a doctor at the Yatharth Super Speciality Hospital in Noida Extension.

The robot, developed by Bengaluru-based start-up Invento Robotics, cost the hospital one million rupees, according to Yatharth Tyagi, director of the company that runs the hospital. Mitra is also being used for remote consultations with specialists to reduce their risk of becoming infected.
